

Playing under a magnifying glass

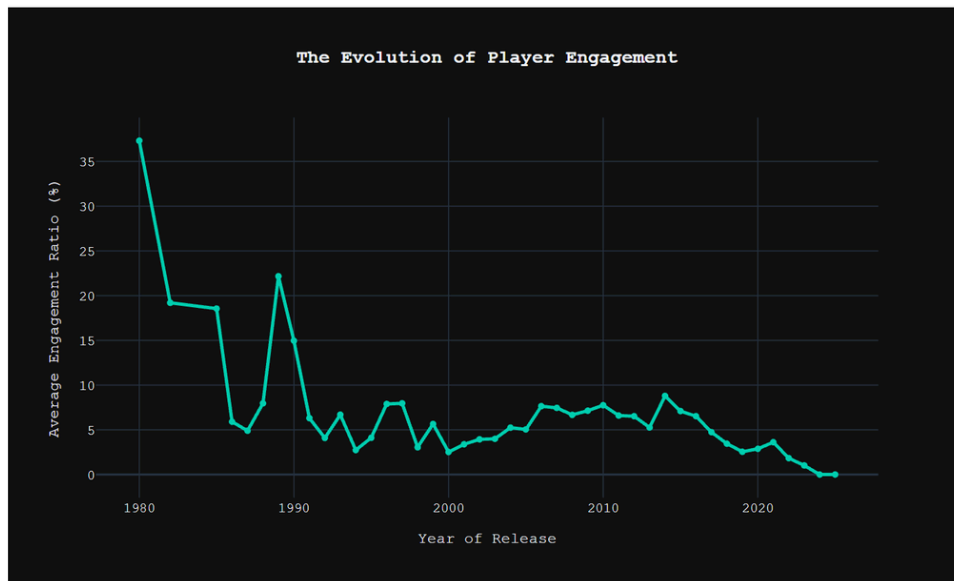

This project goal was to make an analysis about trends shifting through the history of gaming in order to provide strategic insights for decision making in the industry. After cleaning the data and making it useable, the EDA process began with answering the main questions and alongside the common process of getting statistics there was also an advanced analysis that helped seeing deep connections in the raw data. The first conclusion after examining correlations proved that mainstream developer popularity is entirely decoupled from critical success and actual user ratings. The next observation was to realize which genres survived in the test of time, and the results interestingly showed that there is a strong presence that roots in thus entire industry. Lastly i found an interesting paradox with the engagement ratio that suggested that the most complexed and invested games are not necessarily the most popular, that's because gamers tend to neglect high demanding games from a psychological reasons perhaps, and as the time goes by gamer's devotion is decreasing. In the future we will probably see more games that gamers would like to "taste" rather than to fully "digest".

- This graph shows the evolution of games being fully played - as an engagement ratio average of each year.

How learning in Datacamp helped me with the project ?

Learning the courses within Datacamp gave me the fundamental approach to data analysis, it helped me understanding the hierarchy of the EDA process, and also served me a good interactive exercises in a fun way. I used the slides material to refresh my memory and it gave me ideas how to explore the dataset. Lastly and most importantly it taught me how to find connections in a creative way when observing the data of a specific topic.
